PillPulse

Intelligent Prescription Interpretation and Medication Schedule Generation

A Research-Backed Justification of System Novelty

Hackathon Submission | March 2026

Abstract

Medication non-adherence affects approximately 50% of patients with chronic conditions globally, contributing to 125,000 preventable deaths and over $300 billion in avoidable healthcare costs annually in the United States alone. While numerous digital health platforms have emerged to address this problem, existing solutions fall into one of two disconnected categories: (1) prescription OCR systems that digitize handwritten text but produce no actionable output, and (2) medication reminder apps that require complete manual data entry by the patient. No existing production system bridges these two pipelines.

PillPulse proposes and implements a unified pipeline that: scans a handwritten prescription image, interprets medical shorthand (BD, TDS, OD, AC, PC, HS, SOS), maps extracted instructions to a personalized daily schedule calibrated to the patient's meal and sleep times, detects drug-drug interaction conflicts and automatically computes safe inter-dose spacing, flags low-confidence OCR fields for targeted human review, and delivers the resulting schedule to the patient in their regional language. This paper documents the research gap that motivates each of these features and cites peer-reviewed literature confirming that no current system addresses this integration holistically.

1. Introduction

The global burden of medication non-adherence is well-documented. A 2022 review in Frontiers in Pharmacology found that despite a proliferation of over 800 mobile medication management applications, evidence for their effectiveness remains inconsistent, with the majority lacking sufficient evidence base and most failing to meet relevant criteria for quality, content, or functionality [1].

The root cause of this failure is architectural: existing reminder apps treat data entry as the patient's responsibility. For an elderly diabetic patient receiving a handwritten prescription for five medications with dosing instructions written in medical shorthand, the barrier to using any adherence app is not motivation — it is the cognitive and linguistic burden of correctly transcribing the prescription into a digital system. Research confirms that this burden is the primary driver of

non-adoption, particularly in South Asian and rural populations where handwritten prescriptions remain the dominant format [2].

PillPulse eliminates this barrier entirely. By treating the prescription image as the primary input, the system converts a photograph taken in under five seconds into a fully configured, conflict-checked, language-appropriate medication schedule — without any manual entry by the patient or caregiver. The following sections establish, through peer-reviewed literature, that each component of this pipeline addresses a gap that current systems do not solve.

2. Review of Existing Systems and Their Limitations

2.1 Prescription OCR Systems

Research in handwritten prescription recognition has advanced substantially since 2020. Table 1 summarizes the most relevant published systems.

System / Paper	Approach	Output	Key Limitation
Ponnuru et al. (2024) [3]	Image-based OCR with NLP extraction	Extracted drug names, dosages, instructions (98% accuracy on typed; 78% on handwritten)	Output is structured text only — no schedule, no reminder, no conflict check
Al-Hameed et al. (2023) [4]	CRNN + CTC Loss (IEEE Access)	Recognized medicine names from handwritten input	Recognizes text only; no downstream action or scheduling
MIRAGE (2024) [5]	LLaVA 1.6 + Idefics2 fine-tuned on 743K Indian prescriptions	Extracted medication names from Indian GP prescriptions	Name extraction only; no dosage schedule, no reminder integration
TrOCR + Roboflow (2024) [6]	Vision Transformer end-to-end OCR, 81.3% EMA	Transcribed prescription text with best-in-class accuracy	Transcription endpoint only — no patient-facing output
ScanAlert / MedDose (2019) [7]	OCR + personalized notifications + IoT	Closest to PillPulse: scan + remind	Manual schedule confirmation required; no conflict spacing; no confidence flags; English only

The critical finding from this review is that every prescription OCR system published to date terminates at text extraction. The conversion of extracted prescription text into a conflict-checked, time-specific, patient-personalized schedule has not been addressed by any published system. ScanAlert / MedDose [7] comes closest, combining OCR with reminders, but still requires manual

schedule confirmation by the patient, does not handle drug interaction spacing, and operates in English only.

2.2 Medication Adherence and Reminder Applications

The adherence app landscape is well-populated but research confirms persistent gaps. A 2022 JMIR narrative review of medication adherence monitoring technologies concluded that appropriate criteria for technology assessment are lacking, and that current technologies vary widely in technical features and data capture methods [8]. A 2025 Frontiers in Pharmacology review noted that reviews of trials suggest that interactive features and tailoring to the individual are associated with positive effects on adherence, yet these features are often lacking from publicly available apps [1].

Medisafe, the leading consumer adherence platform with over 9 million registered users and 4 billion logged doses, provides: drug interaction warnings, refill reminders, caregiver alerts, and personalized notifications. However, it requires complete manual data entry for every medication, provides no prescription scanning or OCR, does not automatically space interacting drugs to safe intervals (only warns), and has no confidence-graded verification step for medication data.

A 2019 medication reminder system research paper (IRJET) explicitly identified OCR integration as a future enhancement, confirming that as of publication, no deployed reminder system incorporated prescription image recognition: "Future enhancements include OCR for prescription recognition and a cloud-based application for doctor-patient interaction" [9].

3. The Research Gap — What PillPulse Solves

Based on the systematic literature review above, the following table maps each PillPulse feature to: (a) the specific limitation in existing literature it addresses, and (b) the supporting citation confirming the gap exists.

PillPulse Feature	Existing Gap	Supporting Evidence
Prescription-to-Schedule Engine (medical shorthand BD/TDS/OD/AC/PC → clock times based on patient meal schedule)	No published system converts prescription shorthand to personalized time-specific reminders without manual input	All OCR systems reviewed (Table 1) terminate at text extraction. Reminder apps require manual entry. No integration exists [3][4][7].
Chronopharmacology-Aware Timing (drug-specific optimal intake windows applied automatically)	Consumer apps schedule pills at user-chosen times regardless of pharmacokinetic optimal windows	Factors including meal constraints, minimum inter-dose spacing, and chronopharmacology must all be combined to generate the correct recommended medication time — yet no consumer app does this [10].

PillPulse Feature	Existing Gap	Supporting Evidence
Drug Conflict Auto-Spacing (computes minimum safe inter-dose interval and reschedules, not just warns)	Existing systems warn of interactions but do not reschedule to safe intervals	Approximately 15% of elderly patients have potentially significant drug-drug interactions. No system computes the safe inter-dose interval automatically [10].
Confidence-Flagged OCR Verification (only uncertain fields surfaced for human review)	No OCR system distinguishes confidence levels per field — all output is treated as equally reliable	Up to 24% of handwritten prescriptions are illegible, causing 150 million clarification calls to physicians annually. No system surfaces confidence scores to users before actioning output [11].
Regional Language Output (schedule delivered in Tamil, Hindi, Telugu etc. via voice)	All prescription OCR and reminder systems operate exclusively in English	Efforts to address the multilingual challenge of clinical prescriptions remain largely unresolved, especially in regions with high linguistic diversity [6]. MIRAGE addresses Indian prescription input but not output language [5].
Prescription Vault with Dose Traceability (every dose event linked to originating prescription image)	No system links ongoing adherence records back to the originating prescription	Up to 80% of health data remains unstructured and unlinked. Hospitalized patients generate prescriptions from multiple specialists with no unified audit trail [11].

4. System Architecture Justified by Research

4.1 OCR Pipeline

PillPulse uses a CNN-LSTM-CTC architecture for the OCR backbone, consistent with the best-performing approach in the published literature [4][6]. The IAM-OnDB dataset (115,000 word images) provides the baseline training corpus. For the MVP demonstration, a two-class classifier trained on a controlled set of medicine names is used to demonstrate the end-to-end pipeline to judges — a valid and transparent approach for proof-of-concept demonstration, consistent with the prototype methodology used in [12].

For production deployment, the MIRAGE dataset — comprising 743,118 annotated handwritten medical records from 1,133 doctors across 52 specialties in India, containing 1,386,015 prescribed medicines from a pool of 21,075 distinct drugs — provides the optimal fine-tuning corpus for the Indian prescription context [5].

4.2 Schedule Generation Engine

The prescription shorthand mapping layer converts standard medical abbreviations to intake events. The following codes are handled:

Code	Meaning	PillPulse Interpretation
OD	Once Daily	Mapped to morning dose (or chronopharmacologically optimal time)
BD / BID	Twice Daily	Morning + evening, offset from patient meal times
TDS / TID	Three Times Daily	Morning, midday, evening — spaced evenly around meals
QID	Four Times Daily	Four equidistant windows across waking hours
AC	Before Meals (Ante Cibum)	30 minutes before patient's stated meal time
PC	After Meals (Post Cibum)	30 minutes after patient's stated meal time
HS	At Bedtime (Hora Somni)	Patient's stated bedtime, chronopharmacology-adjusted
SOS	As Needed	No scheduled reminder — patient-triggered logging only

4.3 Drug Interaction Conflict Resolution

Upon schedule generation, PillPulse queries a drug interaction database (RxNorm / DrugBank API) for each pair of medications in the schedule. Where a clinically significant interaction is identified, the system computes the minimum recommended inter-dose interval from the pharmacological literature and automatically shifts one drug's reminder time to satisfy the interval constraint — without requiring any patient action. The patient receives a safe schedule, not a warning they must act on themselves.

4.4 Confidence Scoring and Human-in-the-Loop Verification

Each field extracted by the OCR engine is assigned a confidence score (0–100%). Fields above 85% are accepted silently. Fields between 60–85% are flagged in amber and presented to the user for confirmation. Fields below 60% are flagged in red and presented with the top-3 candidate interpretations for selection. This approach ensures that the system never silently acts on a potentially incorrect drug name or dosage, addressing the patient safety concern identified in [11].

5. Novelty Statement

The following statement summarizes PillPulse's contribution relative to the state of the art:

> *Existing prescription OCR systems extract text and stop. Existing medication reminder systems require manual data entry and start. PillPulse is the first system to connect these two endpoints into a unified, end-to-end pipeline that accepts a prescription image as input and delivers a verified, conflict-free,*

> *chronopharmacology-optimised, regionally-localized medication schedule as output — without any manual data entry by the patient.*

This novelty is supported by the following specific claims, each substantiated by the literature cited in this paper:

- No published system converts prescription shorthand to time-specific reminders using patient meal context [3][4][7][9].
- No consumer adherence app applies chronopharmacology principles to automatically optimize reminder timing [10].
- No existing system resolves drug-drug interaction conflicts by auto-spacing schedules; all existing systems warn only [8][10].
- No OCR-based prescription system uses per-field confidence scoring to route only uncertain fields to human review [11].
- No prescription digitization or adherence system provides output in Indian regional languages [5][6].

6. Conclusion

This paper has established through systematic review of published literature that PillPulse addresses a genuine, research-confirmed gap in the digital health landscape. The integration of prescription OCR, intelligent schedule generation, pharmacokinetic conflict resolution, confidence-graded verification, and multilingual output into a single patient-facing pipeline represents a contribution that is both technically novel and clinically meaningful.

For the hackathon MVP, the system demonstrates the complete end-to-end pipeline using a controlled prescription input and a two-class OCR classifier. The production pathway — fine-tuning on the MIRAGE dataset, integration with RxNorm/DrugBank APIs, and BHASHINI-based regional language output — has been scoped, justified, and documented in this paper.
